Lisa R. Markus, De Anza College

The induced path number of a graph \( G \), denoted \( \rho(G) \), is defined as the minimum number of subsets into which the vertex set of \( G \) can be partitioned such that each subset induces a path. In this talk we give the induced path number of certain classes of graphs including paths, cycles and complete graphs as well as their complements. We will also give a Nordhaus-Gaddum type result for the sum of the path partition number of a graph and its complement as well as sharper lower bounds for bipartite graphs and trees.
